WWI	World War One (1914 – 1918)
WWII	World War Two (1939 – 1945)

Glossary of Terms

Cropmark	Differential growth and colour/tone of crops and vegetation over buried features
Earthwork	A large bank of soil which forms a boundary, fortification, or mound
Georectify	Taking an image without a coordinate system and using static points on a known coordinate system to digitally place it within its correct geographical location
Landfall	The point at the coastline at which the offshore export cables are brought onshore, connecting to the onshore cables at the transition joint bay above mean high water
Onshore substation sites	Areas where onshore substations will be situated
Preliminary Environmental Information Report (PEIR) boundary	The boundary of the onshore area which has been assessed for this airborne remote sensing project
Soilmark	Soil marks are differences in soil colour because of the ploughing of buried archaeological feature
Study Area	Area where potential impacts from the project could occur, as defined for each individual EIA topic. In the context of this airborne remote sensing report, the Study Area, is a 100m buffer to the PEIR boundary to allow for landscape context in recording of the remote sensing and historic map regression data.

23.2 AERIAL PHOTOGRAPHIC, LiDAR DATA AND HISTORIC MAP REGRESSION ANALYSIS

23.2.1 Introduction

1. Air Photo Services Ltd (APS) was commissioned to undertake an assessment of Aerial Photographic (AP), Light Detection and Ranging (LiDAR) and satellite imagery, alongside historic map regression analysis, for the Preliminary Environmental Information Report (PEIR) boundary for the Dudgeon and Sheringham Shoal Extension Projects.
2. The analyses were undertaken to provide aerial imagery interpretation and historic map regression data for the following areas:
 - The PEIR boundary; and
 - The Study Area within a 100m buffer to the onshore PEIR boundary.
3. The location of the PEIR boundary is presented on **Figure 23.2-1** which displays the following onshore elements:
 - The PEIR Boundary;
 - The Onshore Substation Sites; and
 - The Study Area, which is a 100m buffer to the PEIR boundary to allow for landscape context in recording of the remote sensing and historic map regression data.
4. This review is required as part of the overall baseline data compilation for the PEIR, to which it forms a Technical Appendix. It is undertaken in accordance with the specification for Onshore Archaeology and Cultural Heritage: Analysis of Aerial Photographic and LiDAR data and Historic Map Regression (Royal HaskoningDHV 2020).
5. This technical report represents the work undertaken by APS between June 2020 and March 2021.

23.2.2 Sources of Data

6. The assessment has systematically examined the following sources of data:
 - Historic and modern aerial photographs *via* online sources;
 - Satellite imagery *via* online sources;
 - Online search of the Cambridge University Collection of Aerial Photographs (CUCAP) database at <https://www.cambridgeairphotos.com/map/> which generates a Comma Separated Value file (CSV) file showing the locations of vertical and oblique aerial photographic surveys and site targets which are shown at **Figure 23.2-2**. This collection remains in long term closure during its digitisation in Cambridge and it is not possible to see any of the actual images at the time of writing. Once again these have been examined by the National Mapping Programme (NMP) in areas where this survey has been completed;

- Search by the Norfolk Historic Environment Record (NHER) of their archive of oblique aerial photographs which was supplied remotely as a metadata-only CSV file. The distribution of these specialist aerial photography is shown at **Figure 23.2-3**;
- Online search of the Aerofilms archive curated by Historic England (HE) at www.britainfromabove.org.uk which did not contain any relevant aerial photographs within the Study Area;
- The Norfolk National Mapping Programme (NMP), which covers part of the Study Area. This NMP coverage is shown at **Figure 23.2-4**. These projects are the Norfolk Coast full NMP July 2002 - January 2006 (Albone *et al* 2007), Norwich – Thetford A11 full NMP April 2006 - August 2007 (Cattermole *et al* 2013) and the Norfolk Aggregates Levy Sustainability Fund (ALSF) full NMP August 2007 - March 2008 (Albone *et al* 2008);
- Environment Agency (EA) and National LiDAR Programme (NLP) 1m resolution 2017 LiDAR data over the whole Study Area as shown at **Figure 23.2-5**;
- Norfolk Historic Environment Record (NHER) data;
- Available Enclosure Maps supplied as digital data by the Norfolk Records Office (NRO);
- Some historic map and full coverage aerial photographic data displayed by the NRO's Map Explorer at www.historic-maps.norfolk.gov.uk. This website dates to 2012 and is only accessible *via* the Internet Explorer web browser. The whole county is covered by mosaics of vertical aerial photographs dating to 1946, taken by the Royal Air Force (RAF) and a colour layer taken in 1988, likely by Geonex; and
- Envirocheck Historical Map reports.

23.2.3 Restrictions to Data Acquisition Due to COVID-19

7. The assessment was undertaken in accordance with COVID-19 secure methodology during a time when the major aerial imagery archives at HE and the NHER at Gressenhall were closed to all visitors.
8. The material held at these archives has been incorporated to the Norfolk NMP in areas where this has been undertaken and to the dates when these surveys were completed.
9. The report is caveated by the absence of consultation of the aerial photographs at HE and NHER due to COVID-19 closures of these facilities for health and safety reasons in accordance with Government guidelines and regulations.

23.2.4 Aims and Objectives

23.2.4.1 Aerial photographic and LiDAR survey

10. The aim of the survey was to provide information on the location and nature of buried and upstanding archaeological features visible on historic aerial photographs, modern aerial and satellite imagery and visualised LiDAR data to assess the buried, topographic and micro topographic features within the Study Area.
11. The analysis aimed to assess the present level of preservation of the buried historic landscape in the study area. This was assessed in respect of the considerable landscape change wrought by a high concentration of defensive features dating to World Wars One and Two (WWI and WWII) and intense arable farming over much of the open land in the Study Area.
12. The objective of this survey is to identify the potential for heritage asset presence and preservation through the assessment of aerial imagery and LiDAR data.
13. This report highlights the key data sources consulted, the methodologies employed, and the results and conclusions drawn from the data acquisition and processing.

23.2.4.2 Map Regression Analysis

14. The aim of the map regression analysis was to collect and present all relevant historic maps, including available Tithe and Enclosure maps where present, Ordnance Survey (OS) and other pre-modern cartographic sources. The objective was to investigate and demonstrate landscape changes within the Study Area over the 19th, 20th and 21st Centuries using cartographic sources derived from the archives listed above. The online catalogues of the National Archive (NA) and British Library (BL) refer the reader back to the archive at the NRO and some maps are not available at this time or are damaged and under conservation. The maps presented in this assessment are those which were available online during the COVID-19 restrictions, which precluded in-person consultations and enquiries.

23.2.5 Methodology

23.2.5.1 Data Type and Sources

15. This survey has utilised a range of sources and archives in order to identify, interpret and map heritage features from the air and from satellites. This section gives details about the methodology employed to search each archive, the type of data available for study and the interpretation methods applied to each data set.

23.2.5.2 Modern Digital Aerial and Satellite-Derived Imagery and Data: Types and Sources Used for This Assessment

23.2.5.2.1 Online Aerial and Satellite-Derived Images

16. Since 1999, digital mosaics of multiple timelines of georeferenced aerial photographs have been uploaded to geoportals such as Google Earth and at Bing.com. The dates attributed to these images are not 100% assured or authenticated, but for heritage survey purposes this has no legal implication in this instance. They are available in real time as open-source imagery online, with some copyright requirements. The imagery may change when new sources are uploaded.

17. All available online aerial and satellite derived images which constitute the open-source mosaics of aerial imagery displayed on Google Earth and Bing.com/ Maps (aerial and birds-eye if available) were consulted for this survey. All timelines available on these geoportals were systematically consulted, between 1st June and 20th October 2020. Following magnification, relevant images were captured at the highest resolution using the 'save-image' function in Google Earth Pro or a screen snipping tool. They were saved, labelled and filed for geo-referencing.
18. Summer timelines at Google Earth, particularly captured in 2006, were very helpful in the recording of crop marked buried sites throughout this Study Area.
19. Aerial images displayed at Bing Maps was used in the same manner but with the limitations that there was a restricted single view timeline and less flexible image capture mechanisms. The Microsoft 'snipping tool' was used to capture the relevant images which generally were not as informative as the comprehensive timeline datasets at Google Earth.

23.2.5.2.2 *Norfolk NMP Data*

20. NMP data were supplied in GIS-ready format *via* AutoCAD Drawing Exchange Format (DXF) files and have been integrated into this survey as separate shapefile layers to maintain the integrity and acknowledgement of the source of these data.

23.2.5.2.3 *Environment Agency LiDAR Data*

21. LiDAR data have been collected from airborne survey platforms in recent years at varying resolutions, and are available for downloading, processing, visualising and interpreting *via* the EA website <https://environment.data.gov.uk/DefraDataDownload/?Mode=Survey> (Environment Agency, 2020).
22. LiDAR data indicates variation in the height of the ground surface. Data is collected by an active laser beam fired in pulses which scans the ground surface. The reflected pulses are recorded by the sensor on board a geolocated airborne survey platform, fitted with an inertial measurement unit to record the roll, pitch and yaw of the aircraft.
23. The point cloud data derived from the survey are processed into a series of Digital Elevation Models (DEM) usually in American Standard Code for Information Interchange (ASCII) format. These include Digital Surface Models (DSM) which contain tree cover and buildings, and Digital Terrain Models (DTM) which remove tree cover and can reveal features beneath the tree canopy (Bennett *et al* 2012; Hesse 2010; Štular *et al* 2012).
24. These data are of assistance in recording micro and macro topographic features which may indicate relict or extant archaeological features and historic landscapes alongside more modern features. LiDAR data are best interpreted and used in conjunction with modern and historic aerial photographs and maps to provide ground truth information for features and sites recorded *via* this prospection method.

25. The data needed were identified by using the EA timestamp shapefile detailing the LiDAR file names within the area of interest and the OS 10km and 5km grid square to identify the grids and quarter sheets. Digital Terrain Models were selected as the primary data source as the ability to remove the tree canopy makes it ideal for prospection. All available LiDAR data for this site were downloaded for completeness of evidence. The metadata for the LiDAR downloaded for this assessment can be seen at **Table 23.2-5**.
26. The whole study area was covered by NLP LiDAR data at 1m resolution with other data available in individual survey areas. A map detailing the LiDAR data coverage can be seen at **Figure 23.2-5**.
27. The data were visualised into Hillshade, Multi Directional Hillshade, Sky View Factor, Slope, Open Positive and Open Negative using the Relief Visualisation Toolbox (RVT) Version 2.2.1. These visualisations were chosen as they are of most use for archaeological prospection. The multiple ASCII tiles were merged before being visualised for ease of use in the GIS. The data were analysed alongside the aerial photographs and base mapping to double check the topography and nature of features interpreted from LiDAR data.
28. An additional visualisation was created using a simplified process based upon the methodology proposed by Hesse to create a Simple Local Relief Model (SLRM) (Hesse, 2010). A low pass filter was applied to nearest neighbour resampling, and the resampled model was removed from the original DTM, creating a Local Relief Model. This was then processed through the RVT with a smoothing factor of 20m.

23.2.5.3 Data Processing

29. The collected digitised photographs and images were labelled and archived and selected frames were georectified to the OS digital map base with the QGIS and ArcGIS georectification tools for interpretation and mapping. The project used an OSGB/1936 British National Grid European Petroleum Survey Group (EPSG):27700 Coordinate Reference System (CRS).
30. Interpretative or source queries were addressed as appropriate by further reference to the archived photographs in the survey files.
31. Following comparison to other airborne sources and all NHER data, extent of area polygons were digitised around the interpreted extent of features identified, and a site database created in QGIS as an attribute table within a shapefile.
32. When all data sources had been examined, interpretative polygons were digitised to further shapefiles to indicate the form, extent and type of extant features within areas.

23.2.5.4 Data Presentation

33. The data were presented in shapefile data format within the project GIS. A shapefile contains geographical reference data as individual objects such as a ditch, a bank, a structure or a coordinate area. Features exist as 'objects' and their 'attributes' where the interpretations are recorded within the shapefile.
34. In addition to the shapefile, the data derived from the survey are presented in the Technical Mapbook sheets 01 – 23 which is indexed at **Figure 23.2-9**.
35. The map book presents keyed, labelled and individually numbered illustrations at a consistent scale.

36. The data are also presented as a gazetteer of sites at Table 23.2-1. The gazetteer is derived from selected attributes within the extent of area mapping shapefile. It summarises the location, type, condition and interpretation of each individually identified site or area of features.

23.2.6 Interpretative Mapping

23.2.6.1 Extent of Area Mapping

37. Extent of area mapping was undertaken initially to identify archaeological assets through 'APS Site Polygons'. These polygons indicate the extent of area around a feature or group of archaeological features. A detailed supporting attribute table was compiled at this stage detailing the following for each feature:
- APS Site Number;
 - DEP SEP ID Number for concordance;
 - Asset Type;
 - Broad Type;
 - NMP coverage;
 - APS derived records;
 - Evidence Type (1-10);
 - Source (1-10);
 - Period;
 - Monument UID Number;
 - Source HER;
 - Comment;
 - By;
 - Supplier;
 - Client;
 - Project;
 - Easting;
 - Northing;
 - National Grid Reference;
 - Map Source; and
 - Map Book Number.
38. This process created a database which forms the basis for all detailed mapping and analysis.
39. Aerial imagery and LiDAR analysis is a non-intrusive survey method, and not all features which are identified may be accurately dated by this means alone.

23.2.7 Assumptions and Limitations

23.2.7.1 Historic Aerial Photographs

40. The assumption that aerial photographic survey and vertical and oblique aerial photographs show all features and will reveal a complete archaeological record in any given area is erroneous. This is due to many interactive survey, seasonal, environmental, meteorological and perception and interpretation issues which are set out below.
41. Interpretation of aerial photographs relies either on visual identification of the effect heritage assets have on crops and other vegetation, marks in soils or visible features or earthworks which are more visible at times of clear low light.
42. It is important to note that aerial photographs usually only show part of the horizontal and vertical extent of buried and upstanding features. Their capacity to reveal features as cropmarks, vegetation marks, soil marks or as the shadows cast by banks, ditches and walls, depends upon several environmental and agricultural factors prevalent at the time of the photographic survey. It is possible for many years' photography over one site to show nothing at all, and then during one instance of survey to reveal complex buried cropmark features. The direction of light at the time of photography, with reference to shadows cast and crop or soil marked features highlighted, can also affect the visibility of features on aerial photographs. Unlike digitally processed LiDAR and other data, the azimuth of the sun cannot be changed on a conventional aerial photograph.
43. Past and present land use also presents limitations to visibility of features. A cropped arable regime of cereals often allows the formation of cropmarks, whereas grassland, unless seen in times of extreme moisture stress, can mask the appearance of buried features. The time of year is thus important in gaining maximum benefit from aerial photographic sorties. In winter, the low leaf index and lower light angle assists visibility of topographic and earthwork features. In summer, ripening crops, often from April through to harvest in July/August, may show differential marks over buried features. Dry conditions will often cause parching in grass, which will then reveal areas of former foundations as the grass dies over the harder less moisture retentive buried features. Following harvest, weathering and ploughing, marks in soil often show where buried archaeological deposits are being actively ploughed and brought to the surface.
44. In Norfolk, the arable areas have been intensively eroded by ploughing. The lighter shallow soils over well drained substrates are conducive to the formation of crop marks over both buried heritage assets and geological anomalies in the substrates.
45. Aerial photographs cannot be used to detect features in heavily wooded areas whilst LiDAR survey may, under conditions of lower leaf index, penetrate gaps in the tree canopy to provide a DTM of the ground surface beneath.
46. In constructing a comprehensive interpretation of the archaeological landscape, it is thus advantageous to examine a range of photographs, taken under a variety of environmental conditions.

47. The aerial photographs taken in the 1940s often recorded extant landscapes which have been altered often beyond recognition by modern development. These historic photos provide a starting point for the assessment of landscape change, in conjunction with the study of historic maps and modern aerial and satellite-derived imagery. The 1946 layer of mosaiced vertical aerial photos taken by the RAF was used for baseline survey at www.historic-maps.norfolk.gov.uk with comparative analysis at the same site from a mosaic of vertical images taken in 1988.
48. The remit of past oblique aerial surveys, the survey areas chosen and the visibility of sites to the aerial archaeologist can often determine the content and coverage of oblique aerial photography. Observer led flights may be heavily biased and may miss features which were present but were not seen or recorded. This is apparent when comparing vertical aerial photographs taken at times when crops were responsive to concurrent oblique observer-led surveys. In these instances, vertical photographs often record much more extensive cropmark landscapes than the observer-led oblique photographs.
49. It is also important to note that the perception of the environment and expectation of what is to be found may often limit the air photo analyst's mental 'openness' to features. This perception factor is mitigated by repeated examination of imagery taken in different years and under different conditions, and by teamwork between two or more interpreters checking the data. 'Photo fatigue' is also a factor in drop-off rates of discovery or perception of features. It is mitigated by alternating activities and personnel, checking interpretations with other team members and taking adequate visual breaks.

23.2.7.2 Online aerial photographs and satellite-derived images

50. Google Earth regularly uploads new images and attributes some images with the name of the provider and a date of capture. These dates are not verified, but for archaeological survey this is not a legally essential element of the metadata. The issue with data derived from geoportals such as Google Earth is that it changes and is added to; it is a dynamic collection of varied mosaiced dated images and varied resolutions of data derived from aerial photography and satellite imagery. During 2017-2018, Google began to capture its own data, and these layers are largely 'unattributed' in terms of provider. The main UK providers to Google Earth include Getmapping, Infoterra and Bluesky, The GeoInformation Group, Maxar and CNES/Airbus. The mosaic 'cuts' where images have been blended together and captured in different seasons are readily apparent, often within the same 'timeline' data.

23.2.7.2.1 Online aerial photographs and satellite-derived images: conclusion

51. The multiple timelines displayed at Google Earth provided a major source of data for this survey, and revealed detailed crop marked evidence, particularly visible on the 2006 timelines.

23.2.7.3 LiDAR Data

52. LiDAR data are collected for multiple environmental and engineering survey purposes and are therefore sometimes not in compliance with optimum timeframes for heritage survey requirements. An optimum LiDAR survey date for recovery of micro and macro topographic heritage data spans late November to mid-March in the northern hemisphere. This is when leaf canopy and vegetation are at their lowest and a higher proportion of bare earth is exposed in both woodland and open areas to ensure that the laser pulses reach and return to and from the ground in sufficient density to record topography to create an accurate and detailed DTM.
53. Whilst of excellent high resolution, some data are not gathered at an optimal time for specific heritage survey purposes, as they are provided to serve the needs of multi-disciplinary surveys. A lower resolution survey captured during the winter months very often provides more data due to the lack of intervening vegetation which prevents sufficient laser points from reaching the ground surface. A low density of vegetation and leaf canopy is essential to the effectiveness of LiDAR survey in that it ensures maximum penetration of light signals to the ground surface in vegetated areas. The LiDAR data are, however, of assistance in recording some micro and more macro topographic features which may indicate relict or extant archaeological features and historic landscapes. They were used over the survey area in multiple visualisations alongside the aerial photographs and satellite image data. LiDAR data are best interpreted and used in conjunction with modern and historic aerial photographs and maps to provide ground truth information, and this was achieved in this survey.
54. For LiDAR data captured during 'leaf / crop on' conditions, less data is recorded due to foliage and vegetation masking the route of the laser. Similarly, areas of water will absorb the laser giving no returned points.
55. The majority of the NLP LiDAR data were collected between October and March, with varied dates for smaller surveys.
56. When the point cloud is processed into a DTM, reduced ground coverage results in a simplified geometry surface interpolated from the few available data points which can obstruct features of interest.
57. The horizontal cell resolution of LiDAR data can also influence the detection rates of archaeological features. This can occur where the spacing of point measurements is sufficiently wide to conceal or reduce the visibility of small archaeological features. This may have affected this assessment in areas where LiDAR data were gathered at 2m, 1m and 50cm resolutions as opposed to the more detailed 25cm resolution data.
58. It is also important to note that LiDAR visualisation techniques are continually developing and advancing. The multiple visualisations now applied to DSM and DTM data *via* the RVT used for this survey are effective in heritage interpretation. Hillshade, and particularly fixed-direction Hillshade, visualisations do not show the correct position of the actual features, only the position of their virtual 'shadows' on the ground. It is thus important to use multiple visualisations of LiDAR data to ensure accurate positioning of recorded features and optimise the results.

23.2.7.3.1 *LiDAR data: conclusion*

59. The majority of the LiDAR data were captured at times of low leaf index; however these data did not reveal consistently significant topographic heritage assets over the whole of this area. This is due to the eroded and buried nature of the crop marked sites which constitute the majority of the aerial evidence which is largely eroded to sub-surface level.
60. Many of the defensive sites have also been dismantled and levelled, however some were recorded effectively *via* LiDAR data.

23.2.7.4 **Aerial Imagery Limitations: Conclusion**

61. Aerial photograph assessments are often based on sequences of historical imagery which provide a series of 'snapshots' of the landscape under different conditions. In contrast, LiDAR and multi-spectral data are typically gathered at a single or series of closely spaced points in time. Levelled features which are now only visible as cropmarks are not usually visible *via* LiDAR data unless they are recorded as substantially differing vegetation heights within a DSM, or the features causing the cropmarks are still extant as micro topographic differences in the ground surface.
62. The limitations of these data sources are appreciated and considered during survey and use of multiple data sources. Multiple times of survey increases the discovery rate and certainty of interpretation from all airborne data sources when they are examined concurrently.

23.2.8 **Environment Within the Study Area**

63. The nature of the environment has a complex effect on both the preservation and visibility of both buried and upstanding features from the air. Many factors combine to influence very marked seasonal and temporal limitations to visibility of cropmarks soil marks and earthworks, and the modern land use, geology and soil types are all major contributing factors to the visibility of heritage assets from airborne and satellite-derived sources.

23.2.9 **Topography and Land Use**

64. The Study Area lies within a flat - gently undulating predominately arable landscape with some areas of military, or former military, land use.
65. There are some areas of heathland at Kelling, and some areas of coppice or deciduous woodland. The Study Area traverses open countryside around small towns and villages, from Landfall at Weybourne southwards towards Hethersett where it crosses the A11 Hethersett bypass and the Breckland Line railway, to the south of the town. The Study Area then directs to the east to terminate between Swardeston and the A140 and the Great Eastern Main railway line, south of Norwich.
66. The River Wensum crosses the study area at Attlebridge, the River Tud crosses between Honington and Easton and the River Yare crosses the area between Marlingford and Barford.
67. The land use is predominantly arable with some areas given over to other crops, grass and outdoor piggeries.

23.2.9.1 Topography and Land Use Conclusion

68. The Study Area presents an optimal environment for early settlement. The soils and substrates are well drained and easily worked and there is optimal access to watercourses with fertile river valley environments. A considerable resource and opportunity is presented by the coast and sea in the north of the Study Area at Weybourne.
69. This is largely an optimum environment for the recording of buried features from the air, particularly as marks in crops following intensive use for cereal and other arable crop production. This is reflected in the high number of sites which were visible on aerial photographs in arable areas.

23.2.10 Geology

70. The drift deposits (Cranfield University 2020, British Geological Survey (BGS) 2020) are largely chalky till, chalky drift and glacio-fluvial drift, with some areas of Fen peat and an area of marine alluvium at the coast.
71. The extent, type and location of these deposits is shown on **Figure 23.2-6**.

23.2.10.1 Geology Conclusion

72. The well drained chalky and drift substrates provided a favourable environment for settlement from prehistoric times to the present day and give rise to free draining soils which are conducive to the formation of cropmarks over buried features in times of mild drought.
73. Marine alluvium and Fen peat may mask some heritage assets in the discrete areas where these deposits are present.

23.2.11 Soils

74. The drift geologies give rise to areas of shallow well drained soils, and there are other areas with some deeper, more moisture retentive deposits. The soils are shown on **Figure 23.2-7**, and have the following associations and characteristics:
- Adventurer's 2 Soil Association, classification 1024b: Fen peat over glacio-fluvial drift and Tertiary cretaceous sand;
 - Beccles 1 Soil Association, classification 711r: seasonally wet loam and clay over chalky till;
 - Burlingham 1 and 3 Soil Associations, classifications 572n and 572p: deep loam over chalky till and glacio-fluvial drift;
 - Felthorpe Soil Association, classification 643d: deep sandy soil over Glaciofluvial till and drift;
 - Hanworth Soil Association, classification 871c: seasonally wet peat to clayey fine silty and loamy soils, which are affected by groundwater.
 - Isleham 2 Soil Association, classification 861b: seasonally wet deep sand over glacio-fluvial peat and drift;
 - Newmarket 2 Soil Association, classification 343g: Deep sandy soil over glacio-fluvial drift;

- Newport 1, 3 and 4 Soil Association, classification 551 d, f and g: Deep sandy soils over glacio-fluvial drift and chalky till;
- Wallsea 2 Soil Association, classification 813g: seasonally wet deep clay over marine alluvium; and
- Wick 2 and 3 Soil Association, classification 541 s and t: Deep loam over glacio-fluvial and aeolian drift and till.

23.2.11.1 Soils Conclusion

75. The soils in the Study Area present a mixed group of substrates with some soils better draining than others, particularly the loams and sand over glacio-fluvial drift and chalky drift and tills.
76. In this area of Norfolk, the chalk substrate within parts of the Study Area is well drained, and crops respond readily to differences in the depth and consistency of the topsoil, over areas where buried ditched and embanked features are present. This effect also applies to anomalies in the consistency of the substrate. Aerial images in this region show widespread marks in crops over large areas of 'patterned ground' which are caused by these geological patterns and anomalies in the chalk (Stephens 1990 121 – 124). These patterns are particularly visible in some areas of the Study Area and are easily discernible from crop marks caused by archaeological features which are more regular and obviously anthropogenic.

23.2.12 Previously Recorded Heritage Assets

23.2.12.1 Sources of Data

77. Information regarding statutorily protected heritage assets has been provided by the National Heritage List for England (NHLE). One site which is Scheduled within the NHLE lies within the Study area and outside of the PEIR Boundary. NHLE 1013097 is a moated site, which lies to the west of Holt Road near Weybourne, 380m south-southwest of Rosedale Farm at APS_145.
78. The NHER PrefRef reference numbers have been used to refer to sites identified by the survey where a PrefRef is available. The NHER data were provided as shapefiles in point, line and polygon format and were loaded into the project GIS for analysis. Not all heritage assets recorded in the NHER and NHLE are likely to be seen *via* aerial sources and as such will not be discussed in detail, alongside listed buildings and other historic landscape based data.
79. The survey results have been concurred to a concurrent desk based heritage assessment (see [Appendix 23.1 – Archaeological Desk Based Assessment](#)).
80. The NHER contains records spanning all periods of prehistory and history, including prehistoric funerary sites, early and later prehistoric settlement and farming sites and artefactual evidence of land use and activity from the prehistoric and Roman periods onwards.
81. The landscape was settled and used in the Medieval period, and post-medieval field systems which comprise the 'bones' of the modern post enclosure landscape are either extant or recently removed.

82. The Study Area was at the forefront of the coastal defence of Britain in WWI and II. Many military sites, defences, training areas and airfields have been identified within the NHER and by the Norfolk NMP. This survey has sought to qualify these records, by recording their present condition. Whilst some features such as pill boxes and some airfields remain; the 20th Century military landscape is now very different to that observed from aerial photographs taken in the 1940s.

23.2.13 Baseline Summary

83. In summary, the NHER data have provided an important overview of the types of sites that are known within the study area and has recorded and highlighted the potential for and types of heritage asset that were likely to be encountered during this assessment of aerial imagery and LiDAR data.

23.2.14 Results

23.2.14.1 Presentation

84. The results from the interpretation and mapping are presented in **Table 23.2-1**. Results are illustrated by **Figure 23.2-9**, an indexed mapbook which shows all sites which have been recorded, in 23 sheets numbered 01-23 from south to north. The fields in **Table 23.2-1** comprise:

- APS Site Id;
- Mapbook sheet;
- Located in PEIR boundary;
- DEPSEP_ID;
- NHER PrefRef;
- Asset Type;
- Condition on latest source;
- Period;
- Interpretation notes;
- Easting coordinates;
- Northing coordinates; and
- Six figure National Grid Reference (NGR).

Table 23.2-1: Sites within the Study Area.

85. This aerial imagery and LiDAR data assessment has recorded 171 areas of interest and archaeological sites within the Study Area, some of which have been recorded previously by the NMP and NHER. These previous interpretations have been incorporated to the GIS database, where they are fully acknowledged and separated from the newly interpreted or augmented site interpretations made by APS.
86. In many instances this assessment has augmented the information and mapping available for the existing sites and has identified a significant number of new sites in areas where NMP mapping has not been undertaken. These areas where no previous assessment of aerial imagery has been completed are illustrated at **Figure 07**, where they are shown as the blank areas between the areas surveyed by the NMP.
87. Newly recorded sites have in this instance been discovered *via* modern digital aerial and satellite imagery which has been accessioned to and displayed at Google Earth between 1999 and 2019.
88. There are likely to be further sites to be recorded from aerial photographs held in the NHER and HE archives. **Figure 23.2-3** indicates locations where the NHER holds aerial photos which have not yet been examined for this assessment.
89. The information is, however, as complete as can possibly be achieved whilst working under restricted access to the physical archives.
90. The assessment has built upon the considerable body of evidence from aerial photographic sources contained within the NMP data derived from three individual Norfolk NMP surveys. New and previously known sites have been recorded which date from the Neolithic to modern periods, including crop marked sites which indicate the presence of likely Roman settlement remains alongside earlier settlement and funerary features and likely Iron Age – Roman settlement and farming features. Many of these sites are recorded as ‘undated’ as they cannot be firmly dated from remote sensing evidence alone.
91. There is a notable absence of extant or crop marked medieval or post medieval ridge and furrow indicative of agricultural land division and use in this period. This has been observed at other sites in Norfolk and is likely ascribed not to absence of land use, but to the erosion of these fields by subsequent agriculture. Some elements of medieval settlement and agriculture, such as tofts, enclosures, headlands and a Scheduled moated site are indicative of medieval settlement and land use in this area.
92. The Study Area has been heavily ploughed and the majority of the crop marked remains do not display any significant microtopography, as evidenced by examination of LiDAR data. There is however obvious potential for the discovery of sub-surface features and deposits in and around the visible foci of crop marked archaeological features.

93. Some military sites may be preserved residually in woodland and elements of former military landscapes are visible as individual extant features, residual crop and grass marked features and parts of former airfields and training grounds. The NMP recorded the WWI and WWII features in detail from 1940s and 1950s aerial photographs in areas where this survey has been undertaken. These features were prevalent in the area at the coast near Weybourne in the 1940s, when they were instrumental to the defence of Britain. Many of these defensive elements have since been removed entirely. This present survey has sought to record their latest observed condition in order to facilitate assessment of the impact of the cable route on areas as they are now, with knowledge of the content of those areas in their original condition at the time of use.

23.2.14.2 Discussion of Sites Recorded Within the PEIR Boundary

23.2.14.2.1 Prehistoric sites within the PEIR boundary

94. The majority of recorded prehistoric sites within the PEIR boundary are eroded and were seen as marks in crop or grass.
95. Some sites are undated and are likely to date from the prehistoric or Roman periods but dating often cannot be proven solely from airborne remote sensing data.
96. A Neolithic long mortuary enclosure was identified at site APS_124 (**Figure 23.2-9** sheet 20) by both this survey and the NMP at Upper Sheringham Common. The site is visible as a crop mark and is likely to be an element of other landscape and funerary features in this area.
97. An undated curvilinear enclosure which may indicate the presence of an eroded Bronze Age round barrow is visible as a crop mark nearby at APS-122 (**Figure 23.2-9** sheet 20). Further sites which are dated firmly or morphologically to the Bronze Age comprise:
- APS_052 (**Figure 23.2-9** sheet 7) is a crop marked ring ditch indicative of a round barrow to the south of the A47 west of Easton; and
 - APS_142 (**Figure 23.2-9** sheet 22) is a crop marked round barrow, recorded by the NMP, which are situated nearer to the coast to the north and south of Weybourne.
98. Rectilinear ditched enclosures and a curvilinear feature identified by the NMP and recorded as APS_093 (**Figure 23.2-9** sheet 13) to the southwest of Cawston lie within the PEIR boundary and adjacent to a 'D' shaped enclosure within the wider Study Area. This site is likely to have been a focus of rural prehistoric, possibly Iron Age settlement, where APS_094 (**Figure 23.2-9** sheet 13) records former boundaries, which may possibly be a prehistoric or later field system to the immediate north of APS_093.

23.2.14.2.2 Roman sites within the PEIR boundary

99. The true extent of the Iron Age – Roman landscape in this area is not reflected in the firmly dated sites recorded by this survey. The majority of features dating to the later prehistoric period and transition to the Roman period which are visible from the aerial imagery consulted for this assessment or by the NMP have been classified as 'undated' prior to further investigation.

100. The area to the north of Cawston carries potential for buried Roman remains, as cropmarked evidence indicates Roman settlement and military features in this area.
101. Site APS_096 (**Figure 23.2-9** sheet 14) is a possible cropmarked enclosure and field system, which may be associated with nearby likely Roman sites.
102. Sites APS_097 and 098 (**Figure 23.2-9** sheet 14) lie in open countryside to the north of Cawston and to the east of Holt Road. Their main visible elements lie outside the Study Area. The core part of APS_098, a straight sided enclosure with terminal defined entrance, lies outside and to the west of the PEIR boundary. APS_097, a likely Roman military and settlement site again lies to the west of the PEIR boundary. Some ditches extend into the PEIR boundary from the core of site 098, but these are likely to be outlying boundaries rather than visible enclosures or buried ditched military features. This area is described here as, whilst the visible core of the complex crop marked remains lie outside the PEIR boundary, they indicate a potential in this area for sub-surface Roman remains which may not be fully visible *via* airborne remote sensing sources.

23.2.14.2.3 *Undated, possibly Prehistoric or Roman, sites within the PEIR boundary*

103. Marks in crops are visible at intervals along the majority of the PEIR boundary, which indicate undated pre-modern settlement enclosures, field and access ways.
104. Notable foci of tracks, boundaries, pits and enclosures are recorded around Little Barningham at APS_106 – 108 and 110-113 (**Figure 23.2-9** sheet 17) and APS_114 and 115 (**Figure 23.2-9** sheet 18), parts of which lie within the PEIR boundary. Elements of this cropmarked landscape are likely to date to the later prehistoric or Roman periods, with some possible medieval or post-medieval field systems and drainage.
105. Further isolated enclosures, ditches and tracks along the PEIR boundary indicate the presence of pre-modern features. Again, this landscape is likely to have been more extensive than shown by the crop marked evidence.

23.2.14.2.4 *Medieval and Medieval-Post Medieval sites within the PEIR boundary*

106. Whilst medieval settlements and a moated site are recorded in the wider Study Area, no Medieval settlement sites are recorded from airborne remote sensing sources directly within the PEIR boundary.
107. Other sites dated to this period comprise boundaries, tracks and headlands to medieval ploughing.
108. It is noteworthy that there are few traces of extant or eroded ridge and furrow field systems recorded during this assessment. It is likely that the medieval fields may have been ploughed out by later intense agricultural land use.
109. Post-medieval field boundaries, which have been removed to enable mechanised agriculture, are visible in places on aerial imagery and *via* visualised LiDAR data.
110. The post medieval landscape and the enclosed fields are best represented by the 18th and 19th Century Enclosure maps discussed and presented in the Map Regression Analysis within this report (**Section 23.2.16**).

23.2.14.2.5 *Modern sites within the PEIR boundary*

111. The area within the PEIR boundary formed part of Britain's front line coastal and hinterland defence area, particularly during WWII (1939 – 1945) and beyond into the 1950s and Cold War. Defensive training areas, camps, training airfields, pillboxes, coastal and land defences and ordnance training sites are recorded in detail by the NMP and by APS.
112. As stated above, when discussing the wider Study Area, some military sites may be preserved residually in woodland, and elements of former military landscapes are visible as individual extant features (particularly pillboxes), residual crop and grass marked features and parts of former airfields and training grounds. The NMP recorded the WWI and WWII features in detail from 1940s and 1950s aerial photographs in areas where this survey has been undertaken. These features were prevalent in the area at the coast to the north and northwest of Weybourne in the 1940s, when they were instrumental to the defence of Britain at and around Weybourne Camp and its ancillary training and defensive facilities, APS_156, 159, 161, 162, 164 and 168 (**Figure 23.2-9** sheet 01). Many of these defensive elements have since been removed entirely and were concentrated at the coastal area.
113. This present survey has sought to record their latest observed condition in order to facilitate assessment of the impact of the onshore development area on areas as they are now, with knowledge of the content of those areas in their original condition at the time of use which has been provided in detail by the NMP using contemporary aerial photos.
114. The PEIR boundary also contains remains of a military airfield at APS_089 and 90, former RAF Swannington (**Figure 23.2-9** sheet 12) where grass and cropmarked remains of access and runways are visible.
115. Some of the residual eastern parts of the disused RAF/USAAF WWII airfield at Attlebridge also lie within the study area to the west of the PEIR boundary at APS_066. Many of the original dispersals and accessways have been removed, and these are recorded as former hardstanding areas which in places are visible as crop or grass marks, and as extant features from contemporary 1940s aerial photographs at APS_065, 066 and as possible structural evidence at 067 (**Figure 23.2-9** sheet 09).

23.2.15 Conclusion

116. Aerial photographs and LiDAR survey data gathered between the 1940s and the present time show a former landscape of buried eroded cropmark features across the study area.
117. Features dating to the prehistoric, medieval, post-medieval and modern periods have been identified and mapped. Some of these features have been previously identified by the NHER and in areas where NMP survey has been undertaken.
118. In many cases this assessment has augmented and added to these data from modern airborne and satellite imagery sources.

119. It is obvious that the below-ground archaeological deposits which cause the marks in crops and grass in this area are more extensive, both horizontally and vertically, than shown *via* the aerial imagery. Absence of cropmark evidence, due to the limitations detailed above, does not necessarily indicate an absence of archaeological deposits in apparently blank areas.
120. The separation of dating into specific periods of prehistory and history can only be confirmed by ground-based or documentary analyses, but some dating evidence for sites within the Study Area has been proposed by the NMP and by observation of morphological characteristics of crop marked sites.
121. From an aerial perspective, this landscape may be analysed in a 'living' manner as one which developed over time and contains many multi-period elements. These will be more deeply stratified and extensive below the ground than is apparent in the results of the survey. The remains visible as cropmarks are all likely to have been impacted by agricultural cultivation, to some degree, with little or no micro-topographic features visible on the ground.
122. This assessment has identified a range of features and has highlighted the potential for heritage assets within the Study Area and its immediate environs.
123. It leads into and has benefited from a concurrent study of historic maps, which detail the development of the landscape over the past two centuries. This map regression study is presented below ([Section 23.2.16](#)).

23.2.16 Map Regression Analysis

124. An historic map regression study was undertaken concurrent with the aerial imagery and LiDAR analysis to provide understanding of the development of the modern landscape.

23.2.17 Aims and Objectives of the Map Regression Analysis

125. The aim of the map regression analysis was to collect all relevant historic maps, including, Tithe and Enclosure maps where present, in areas where Ecclesiastical Parishes levied Tithes, followed by OS and other pre-modern and modern cartographic sources.
126. The objective was to investigate and demonstrate any landscape changes within the Study Area over the 19th, 20th and 21st Centuries using maps derived from the sources listed at [Section 23.2.2](#) above.

23.2.18 Cartographic Sources

23.2.18.1 Tithe Maps

127. Where available the Tithe maps are displayed at www.historic-maps.norfolk.gov.uk, and the configuration of the fields, accessways and landscape is rural, enclosed and reflected in the patterns depicted on the available enclosure maps. They represent the foundation of the Post-Medieval landscape, and some of the boundaries changed configuration between their depiction on the earlier Tithe and Enclosure maps and by the OS in the late 19th Century. Capturing the Tithe maps as screenshots was evaluated and trialled to provide figures for this report. However, the resolution when captured and georeferenced was inappropriately coarse to determine meaningful detail as remotely accessed screen captures.

23.2.18.2 Enclosure Maps

128. **Figure 23-10** presents an index to the Enclosure mapbook **Figure 23-11**. Available Enclosure maps were supplied by the NRO from Deposit C/Sca 2 as .jpg files. None were available online at www.historic-maps.norfolk.gov.uk within the Study Area and PEIR boundary.
129. Some maps are not held in the NRO deposit C/Sca2 and are referred back to the NRO from the National Archive online catalogue. These items cannot be located by either archive.
130. **Table 23.2-2** lists and comments on the available Enclosure maps.

Table 23.2-2: Analysis of available Enclosure maps

Parish	Enclosure map ref. no. (deposited with Norfolk Quarter sessions only)	Date	Mapbook sheet no	APS notes on Enclosure map
Hethersett	Not stated	1799	1	The area of the PEIR boundary traverses rural enclosed fields and an open area which may be common land in Hethersett parish in 1799
Great Melton	C/Sca 2/195	1826	2	The Great Melton Enclosure map indicates a rural environment of enclosed fields with details of private and public roads in 1826
Wrappingham	Not stated	1815	3	The area of the PEIR boundary just traverses the eastern part of the mapped enclosed land in Wrappingham parish. The map depicts rural enclosed fields
Barford	C/Sca 2/12	1816	4	The Barford Enclosure map indicates a rural environment of enclosed fields and a public road in 1816. The PEIR boundary traverses the northeast edge of the parish
Marlingford and Colton	C/Sca 2/191	1863 and 1804	5	The Marlingford and Colton Enclosure maps indicates again a rural landscape of enclosed fields in the PEIR boundary
Weston Longville	Not stated	1825	6	The PEIR boundary traverses rural enclosed fields and an area of scrubby woodland at Weston Breck within the enclosed parts of Weston Longville
Morton on the Hill (32)	C/Sca 2/155	1826	7	The area of the PEIR boundary traversed rural enclosed fields with some small areas of woodland and a public road in 1826

Parish	Enclosure map ref. no. (deposited with Norfolk Quarter sessions only)	Date	Mapbook sheet no	APS notes on Enclosure map
Swannington	C/Sca 2/282 and C/Sca 2/283	1852	8	The PEIR boundary traverses an area which was laid to rural enclosed fields in 1852
Brandiston	Not stated	1852	9	The area of the PEIR boundary traversed rural enclosed fields through Brandiston parish in 1952
Cawston	C/Sca 2/68	1801	10	The Cawston Enclosure map indicates a rural environment with enclosed fields in 1801
Oulton	C/Sca 2/178	1823	11	In 1823, the land within the PEIR boundary at Oulton comprised rural enclosed fields
Little Barningham	C/Sca 2/166	1832	12	The Little Barningham Enclosure map indicates that the PEIR boundary lay within rural fields, traversed a public road and crossed named fields at Patch Piece and Dog Lover Close to the south of Dog Lane
Bodham	C/Sca 2/45	1810	13	The Bodham Enclosure map indicates a rural environment of enclosed fields where the PEIR boundary traverses the parish to the south of Weybourne
West Beckham	C/Sca 2/20	1843	14	A small part of enclosed land mapped in West Beckham lies within the area of the PEIR boundary and is laid to enclosed rural fields at a farm tenanted or owned by Benjamin Emery
Kelling	C/Sca 2/241	1854	15	Kelling parish was part enclosed fields and part heathland. The mapped area in Kelling lies just to the west of the PEIR boundary and shows a rural agricultural landscape

23.2.18.3 Historic Ordnance Survey Maps

131. **Figures 23.2-12 – 18** present the Historic OS mapping which was published between 1885 and 1995. Historic OS map data are used to illustrate the landscape at the following survey or revision dates:

- 1885 – 1887
- 1907 – 1908
- 1923 – 1929
- 1938 – 1952
- 1957
- 1973 – 1977
- 1994 – 1995

23.2.18.3.1 1885 – 1887 **Figure 23.2-12**

132. The PEIR boundary predominately traverses smaller enclosed rural fields and localised deciduous woodlands and coppices in the late 19th Century. By this date, the foundations of the modern landscape as we see it today had been formed, with a continuous landscape of adjacent fields and farms.

133. The maps depict the Great Eastern and the Eastern Midlands Railway lines to the north of Ketteringham (**Figure 23.2-12** sheets 1 and 2).

134. The rural landscape to the north of Bodham and Kelling Heath to Weybourne (**Figure 23.2-12** sheet 9) contains a mapped depiction of a Scheduled moated site within the Study Area but not within the PEIR boundary.

135. These early OS maps present a clear insight into the pre-WWI and WWII countryside, particularly near the coast, which was heavily defended in the early to mid-20th Century.

23.2.18.3.2 1907 – 1908 (**Figure 23.2-13**)

136. These maps are largely a revision to the first editions, and do not show that the countryside has undergone significant change in the first decade of the 20th Century. The Midland and Great Northern Joint Railway was developed since 1887 and in 1907 – 08 is extant near Attlebridge and the Midland and Great Northern Railway is still extant to the east of Heydon (**Figure 23.2-13** sheet 6) and at Weybourne. (**Figure 23.2.13** sheet 9).

23.2.18.3.3 1923 – 1929 (**Figure 23.2-14**)

137. No major change to the rural landscape was depicted by the OS since 1885 – 87 in the areas covered by the 1920s revision of the First Edition mapping.

23.2.18.3.4 1938 – 1952 (**Figure 23.2-15**)

138. The same rural landscape is depicted between 1938 and 1952, with some gaps in the mapping, and no direct mapping of military airfields. The structures at Weybourne military camp, which were recorded by the NMP from aerial imagery, are depicted for the first time on this map edition (**Figure 23.2-15** sheet 9).

23.2.18.3.5 1957 (**Figure 23.2-16**)

139. The 1957 map depicts the same rural features as previous editions, with the addition of WWII airfields. Part of RAF Attlebridge is depicted (**Figure 23.2-16** sheet 4) as is RAF Swannington, which is depicted in full, with runways and dispersals and is labelled as disused (**Figure 23.2-16** sheet 5).
140. RAF Oulton is similarly depicted and labelled as disused to the north of the PEIR boundary at Oulton (**Figure 23.2-16** sheet 6).
141. Kelling and Weybourne Heaths are depicted in a largely unchanged landscape around Weybourne in the north with unsurprisingly little indication of the once-extensive defensive features at the coast beyond depiction of the structures at Weybourne Camp (**Figure 23.2-16** sheet 9).

23.2.18.3.6 1973 – 1977 (**Figure 23.2-17**)

142. The 1973 – 1977 revision of the OS mapping departed from the traditional depictions utilised in the earlier editions, and adopted a metric grid at 1:10,000 scale. The mapping coverage is not quite complete. It shows that the railway at Weybourne was dismantled (probably in the 1960s) and the area of Weybourne Camp was then depicted as a disused camp with access ways and some mapped structures (**Figure 23.2-17** sheet 8).
143. The same rural landscape is indicated along the PEIR boundary as on earlier map editions.

23.2.18.3.7 1994 – 1995 (**Figure 23.2-18**)

144. This is a somewhat stylised ‘modern’ map which indicates some removed boundaries as confirmed by the aerial imagery.

23.2.18.4 Map Regression Conclusion

145. The landscape within this Study Area is rural, and has largely been under arable cultivation, with woodland and heath or breckland in parts since first observed on maps in the late 18th Century.
146. Railway lines have been constructed and dismantled, alongside some WWII airfields and the defensive camp at Weybourne. Small hamlets, farms and settlements have developed moderately over the last two centuries.
